

Microdermabrasion Stratford

Microdermabrasion Stratford - The condition of Dermatitis Herpetiformis is a chronic skin condition characterized by blisters filled with a watery fluid. It is also known as DH or Duhring's Disease. The name implies the meaning in that it is a skin disease that has the specific appearance similar to herpes, though, the condition is not caused by or related to the herpes virus. DH was initially described during the year 1884 by Dr. Louis Duhring, therefore the name. In the year 1867, a correlation between celiac disease or gluten intolerance and DH was recognized. In the majority of cases, the age of onset is normally 15 to 40 years, though, DH can likewise affect the elderly as well as kids. Men and women are equally affected. The prevalence of DH varies from 1 in 400 to 1 in 10,000.

Indications

DH has a characteristic rash which contains chronic papulovesicular eruptions and is extremely itchy. Usually, this rash is distributed symmetrically on extensor surfaces like for example the elbows, knees, back, back of neck and buttocks. The blisters can vary from being up to 1 cm across to extremely small. As this particular condition is very itchy intensive, the need to scratch can be overwhelming. This can cause the sufferer to really scratch blisters off before they could be checked by a doctor. Intense itching or intense burning sensation are sometimes felt prior to blisters appearing in a particular part.

If left untreated, the severity of DH could considerably change sooner or later. Generally, the symptoms firstly appear in the early years of adulthood, often between 20 and 30 years old. The first noticeable symptoms are the small papules or vesicles that resemble bumps or blisters. The first symptoms are intensive itching and burning. Normally, the very first blisters appear on the shoulders, on the lower end of the spinal column, along the hairline and at times in the mouth. Rarely, does the rash happen on various mucous membranes other than the lips or the mouth. If gluten ingestion is prevented and the proper treatment is provided, the symptoms often disappear. In some cases, taking oral contraceptives could worsen the signs.

The signs of DH tend to come and go, in short periods of time, yet are always persistent. These signs can be accompanied by abdominal pain and fatigue and several indications of celiac disease.

The rash that is caused by DH forms and disappears in 3 stages. Firstly, the patient can see a slight discoloration of the skin where the lesions appear. Next, the skin lesions transform into noticeable papules and vesicles that are likely to happen in groups. The healing stage of the lesions is the final stage of development. Usually this set of signs is characterized by a skin color change. This can result in parts of the skin turning lighter or darker compared to the color of the skin elsewhere on the body. Because of the intense itching, individuals generally scratch that can result in the formation of crusts.
